

The WinAscent line is usually the highest extent of any glyph in the font. If any glyph outlines extend beyond it, character tops may be cropped in Windows Applications.

This area between the WinAscent line and the TypoAscender is used by accents

The ascender is the top of lowercase letters like b, d, and l. It is often higher than the Caps Height, but it does not have to be.

The Caps Height is the top of uppercase letters. It is calculated for the font from H. Rounded letters like O and Q should overshoot it slightly.

The x-height is the top of lowercase letters. It is calculated for the font from x. Rounded letters like c and o should overshoot it slightly.

The superscript y offset is the recommended baseline for superscripts.

The strikeout position defines the top of the rule used for struck-out text. Its thickness and position should be designed so that the text is still legible.

The baseline is the origin from which other distances are measured. Rounded or pointed letters should overshoot it slightly.

The advance width of a letter is the sum of the glyph width and the side-bearings.  
Combining accents often have zero advance width and a negative left side-bearing.  
Lowercase f often has a negative right side-bearing.

The underline position defines the top of the rule used for underlined text. Its thickness and position should be designed not to obscure the descenders in the font

The subscript y offset is the recommended baseline for superscripts.

The descender is calculated from the bottom of lowercase p. If it extends beyond the WinDescent, glyphs may be cropped at the bottom.
